eHealth and health care service system - Part 2. Practical examples

Drag the words to correct boxes.

There are many different eHealth services available. Different *digital care pathways* are gaining ground as there is a need to reach and treat faster a growing number of patients. eHealth brings new ways for patients to seek *health-related information*. The problem with different websites is that while there is a lot of information available online *the quality* of it can vary a lot. Portable medical devices and *wearable technology* bring new ways for patient to generate and collect health data and for healthcare professionals to monitor it *remotely*. eHealth also changes the way patient can access healthcare: one example of this are different *chat services*. It is important to acknowledge that *remote consultations* are not suitable for all kind of situations: patients must be *motivated* to use the services and sudden *severe* conditions still require traditional face-to-face meeting and *physical examination*. In the end, the biggest challenge with successful implementation of eHealth services is to change processes and *working methods* in healthcare organisations to be compatible with new procedures.
